(54) VARIANT PHOSPHOENOLPYRUVATE CARBOXYLASE, GENE THEREOF, AND PROCESS FOR PRODUCING AMINO ACID

(57) A variant phosphoenolpyruvate carboxylase that is not substantially inhibited by aspartic acid is produced by introducing a variant phosphoenolpyruvate carboxylase gene, such as one wherein the 625th glutamic acid residue from the N-terminus of the carboxylase has been replaced by a lysine residue or one wherein the 438th arginine residue has been replaced by a cysteine residue, into *Escherichia coli* or a coryneform bacterium. An amino acid can efficiently be produced by using this carboxylase.

TECHNICAL FIELD

The present invention relates to a mutant phosphoenolpyruvate carboxylase, a gene coding for it, and a production method of an amino acid, and in particular relates to a gene having mutation to desensitize feedback inhibition by aspartic acid, and utilization thereof.

BACKGROUND ART

Phosphoenolpyruvate carboxylase is an enzyme which is found in almost all bacteria and all plants. The role of this enzyme resides in biosynthesis of aspartic acid and glutamic acid, and supply of C4 dicarboxylic acid to the citric acid cycle for maintaining its turnover. However, in the fermentative production of an amino acid using a microorganisms, there have been few reports on effects of this enzyme has not been made clear (Atsushi Yokota and Isamu Shiio, Agric. Biol. Chem., 52, 455-463 (1988), Josef Cremer et al., Appl. Environ. Microbiol.,57, 1746-1752 (1991), Petra, G. Peters-Weintisch, FEMS Microbiol. Letters, 112, 269-274 (1993)).

By the way, the amino acid is a compound which universally exists in cells as components of proteins, however, for the sake of economic energy metabolism and substance metabolism, its production is strictly controlled. This control is principally feedback control, in which the final product of a metabolic pathway inhibits the activity of an enzyme which catalyzes the earlier step of the pathway. Phosphoenolpyruvate carboxylase also undergoes various regulations in expression of its activity.

For example, in the case of phosphoenolpyruvate carboxylase of microorganisms belonging to the genus <u>Coryne-bacterium</u> or the genus <u>Escherichia</u>, the activity is inhibited by aspartic acid. Therefore, the aforementioned amino acid biosynthesis, in which phosphoenolpyruvate carboxylase participates, is also inhibited by aspartic acid.

In the prior art, various techniques have been developed for efficient production in amino acid fermentation, and fermentative production has been carried out for leucine, isoleucine, tryptophan, phenylalanine and the like by using mutant strains converted to be insensitive to feedback control. However, there has been known neither mutant phosphoenolpyruvate carboxylase converted to be insensitive to inhibition by aspartic acid, nor attempt to utilize it for fermentative production of amino acids of the aspartic acid family and the glutamic acid family.

On the other hand, ppc gene, which is a gene coding for phosphoenolpyruvate carboxylase of <u>Escherichia coli</u>, has been already cloned, and also determined for its nucleotide sequence (Fujita, N., Miwa, T., Ishijima, S., Izui, K. and Katsuki, H., <u>J. Biochem.</u>, 95, 909-916 (1984)). However, there is no report of a mutant in which inhibition by aspartic acid is desensitized.

The present invention has been made from the aforementioned viewpoint, an object of which is to provide a mutant phosphoenolpyruvate carboxylase with substantially desensitized feedback inhibition by aspartic acid, a gene conding for it, and a utilization method thereof.

DISCLOSURE OF THE INVENTION

As a result of diligent investigation in order to achieve the aforementioned object, the present inventors have found that the inhibition by aspartic acid is substantially desensitized by replacing an amino acid at a specified site of phosphoenolpyruvate carboxylase of <u>Escherichia coli</u> with another amino acid, succeeded in obtaining a gene coding for such a mutant enzyme, and arrived at completion of the present invention.

Namely, the present invention lies in a mutant phosphoenolpyruvate carboxylase, which originates from a microorganism belonging to the genus <u>Escherichia</u>, and has mutation to desensitize feedback inhibition by aspartic acid, and a DNA sequence coding for the mutant phosphoenolpyruvate carboxylase.

The present invention further provides microorganisms belonging to the genus <u>Escherichia</u> or coryneform bacteria harboring the DNA fragment, and a method of producing an amino acid wherein any of these microorganisms is cultivated in a preferable medium, and the amino acid selected from L-lysine, L-threonine, L-methionine, L-isoleucine, L-glutamic acid, L-arginine and L-proline is separated from the medium.

Incidentally, in this specification, the DNA sequence coding for the mutant phosphoenolpyruvate carboxylase, or a DNA sequence containing a promoter in addition thereto is occasionally merely referred to as "DNA sequence of the present invention", "mutant gene" or "phosphoenolpyruvate carboxylase gene."

The present invention will be explained in detail hereinafter.

(1) Mutant phosphoenolpyruvate carboxylase

10

20

25

30

45

50

The mutant phosphoenolpyruvate carboxylase of the present invention (hereinafter simply referred to as "mutant enzyme") lies in the phosphoenolpyruvate carboxylase of the microorganism belonging to the genus <u>Escherichia</u>, which has mutation to desensitize the feedback inhibition by aspartic acid.

Such mutation may be any one provided that the aforementioned feedback inhibition is substantially desensitized without losing the enzyme activity of the phosphoenolpyruvate carboxylase, for which there may be exemplified mutation which, when a mutant phosphoenolpyruvate carboxylase having the mutation is allowed to exist in cells of a microorganism belonging to the genus <u>Escherichia</u>, gives the cells resistance to a compound having the following properties:

it exhibits a growth inhibitory action against a microorganism belonging to the genus <u>Escherichia</u> which produces a wild type phosphoenolpyruvate carboxylase;

the aforementioned growth inhibitory action is recovered by existence of L-glutamic acid or L-aspartic acid; and it inhibits wild type phosphoenolpyruvic carboxylase activity.

More concretely, there may be exemplified, as counted from the N-terminus of the phosphoenolpyruvate carboxy15 lase:

- (1) mutation to replace 625th glutamic acid with lysine;
- (2) mutation to replace 222th arginine with histidine and 223th glutamic acid with lysine, respectively;
- (3) mutation to replace 288th serine with phenylalanine, 289th glutamic acid with lysine, 551th methionine with isoleucine and 804th glutamic acid with lysine, respectively;
- (4) mutation to replace 867th alanine with threonine;
- (5) mutation to replace 438th arginine with cysteine; and
- (6) mutation to replace 620th lysine with serine.

Incidentally, as the phosphoenolpyruvate carboxylase of the microorganism belonging to the genus <u>Escherichia</u>, an amino acid sequence, which is deduced from a phosphoenolpyruvate carboxylase gene of <u>Escherichia coli</u> (Fujita, N., Miwa, T., Ishijima, S., Izui, K. and Katsuki, H., <u>J. Biochem.</u>, 95, 909-916 (1984)), is shown in SEQ ID NO:2 in the Sequence listing. In addition, an entire nucleotide sequence of a plasmid pT2, which contains the phosphoenolpyruvate carboxylase gene of <u>Escherichia coli</u>, is shown in SEQ ID NO:1 together with the amino acid sequence.

The aforementioned mutant enzymes are encoded by DNA sequences of the present invention described below, which are produced by expressing the DNA sequences in <u>Escherichia coli</u> and the like.

(2) DNA sequence of the present invention and microorganisms harboring the same

The DNA sequence of the present invention is DNA sequences coding for the aforementioned mutant enzymes, and has mutation to desensitize feedback inhibition of phosphoenolpyruvate carboxylase by aspartic acid in coding regions in DNA fragments coding for phosphoenolpyruvate carboxylase of the microorganism belonging to the genus Escherichia.

Concretely, there may be exemplified a DNA Sequence coding for the phosphoenolpyruvate carboxylase having the mutation of any one of the aforementioned (1) to (6), for example, with respect to the nucleotide sequence of SEQ ID NO:1, there may be exemplified a DNA sequence having any one of:

- i) mutation to convert GAA of base Nos. 2109-2111 into AAA or AAG;
- ii) mutation to convert CGC of base Nos. 900-902 into CAT or CAC, and GAA of 903-905 into AAA or AAG, respectively:
- iii) mutation to convert TCT of base Nos. 1098-1100 into TTT or TTC, GAA of 1101-1103 into AAA or AAG, ATG of 1887-1889 into ATT, ATC or ATA, and GAA of 2646-2648 into AAA or AAG, respectively;
- iv) mutation to convert GCG of 2835-2837 into any one of ACT, ACC, ACA and ACG; and
- v) mutation to convert CGT of 1548-1550 into TGT or TGC; and
- vi) mutation to convert AAA of 2094-2096 into TCT, TCC, TCA or TCG.

Such a mutant gene is obtained such that a recombinant DNA, which is obtained by ligating a phosphoenolpyruvate carboxylase gene as a wild type enzyme gene or having another mutation with a vector DNA adaptable to a host, is subjected to a mutation treatment, to perform screening from transformants by the recombinant DNA. Alternatively, it is also acceptable that a microorganism which produces a wild type enzyme is subjected to a mutation treatment, a mutant strain which produces a mutant enzyme is created, and then a mutant gene is screened from the mutant strain. For the mutation treatment of the recombinant DNA, hydroxylamine and the like may be used. Further, when an microorganism itself is subjected to a mutation treatment, a drug or a method usually used for artificial mutation may be used.

Further, in accordance with methods such as the Overlapping Extension method (Ho, S. N., Hunt, H. D., Horton, R. M., Pullen, J. K. and Pease, L. R., <u>Gene.</u> 77, 51-59 (1989)), the site specific mutation method (Kramer, W. and Frits, H. J., <u>Meth. in Enzymol.</u>, 154, 350 (1987); Kunkel, T. A. et al., <u>Meth. in Enzymol.</u>, 154, 367 (1987)) and the like, the aforementioned mutant gene can be also obtained by introducing mutation such as amino acid replacement, insertion, deletion and the like into a phosphoenolpyruvate carboxylase gene as a wild type enzyme gene or having another mutation. These methods are based on a principle that a non-mutated gene DNA is used as a template, and a synthetic DNA containing a mismatch at a mutation point is used as one of primers so as to synthesize complemental strands of the aforementioned gene DNA, thereby mutation is introduced. By using these methods, it is possible to cause intended mutation at an aimed site.

Alternatively, a sequence, which has restriction enzyme cleavage ends at both termini and includes both sides of a mutation point, is synthesized, and exchanged for a corresponding portion of a non-mutated gene, thereby mutation can be introduced (cassette mutation method).

The phosphoenolpyruvate carboxylase gene, which is the wild type enzyme gene or has another mutation to be used for introduction of mutation, may be any one provided that it is a gene coding for the phosphoenolpyruvate carboxylase of the microorganism belonging to the genus <u>Escherichia</u>, which is preferably determined for its base sequence and cloned. When it has not been cloned, a DNA fragment containing the gene can be amplified and isolated by using the PCR method and the like, followed by using a suitable vector to achieve cloning.

As the gene as described above, for example, there may be exemplified a gene of <u>Escherichia coli</u> having been cloned and determined for its base sequence (Fujita, N., Miwa, T., Ishijima, S., Izui, K. and Katsuki, H., <u>J. Biochem.</u>, 95, 909-916 (1984)). The sequence in the coding region of this gene is as shown in SEQ ID NO: 1 (base Nos. 237-2888).

Screening of a host harboring the mutant gene can be performed by using an analog compound of aspartic acid. The analog compound preferably has the following properties. Namely, it exhibits a growth inhibitory action against a microorganism belonging to the genus <u>Escherichia</u> which produces a wild type phosphoenolpyruvate carboxylase, the aforementioned growth inhibitory action is recovered by existence of L-glutamic acid or L-aspartic acid, and it inhibits wild type phosphoenolpyruvate carboxylase activity.

If a mutant strain beeing resistant to the analog compound mentioned above is selected from microorganism belonging to the genus <u>Escherichia</u>, for example, <u>Escherichia coli</u> HB101 producing wild type phosphoenolpyruvate carboxylase using inhibition of growth of the microorganism as an index, it is much likely to obtain a host microorganism which produces phosphoenolpyruvate carboxylase with desensitized feedback inhibition by aspartic acid.

It is proposed, as a general structure of an inhibitor of phosphoenolpyruvate carboxylase, that a C4 dicarboxylic acid structure is essentially provided. From such a viewpoint, various compounds were subjected to screening by the present inventors. Escherichia coli HB101 was cultivated in an LB medium, and transferred to M9 media (containing 20 μ g/ml of thiamine and 3 μ g/ml of each of Leu and Pro) containing any one of DL-2-amino-4-phosphonobutyric acid, bromosuccinic acid, meso-2,3-dibromosuccinic acid, 2,2-difluorosuccinic acid, 3-bromopyruvic acid, α -ketobutyric acid, α -ketoadipinic acid. DL-threo- β -hydroxyaspartic acid. L-aspartic acid β -metyl ester. α -metyl-DL-aspartic acid, 2,3-diaminosuccinic acid or aspartic acid- β -hydrazide, and absorbance of the medium was measured at 660 nm with the passage of time, thereby growth was monitored.

Further, when these compounds were present at their growth inhibitory concentrations, it was investigated whether or not the inhibition was recovered by addition of nucleic acids (each of uridine, adenosine: 10 mg/dl), glutamic acid or amino acids of the aspartic acid family (Asp: 0.025 %, each of Met, Thr, Lys: 0.1 %).

As a result, three compounds: 3-bromopyruvate (3BP) (1), aspartate-β-hydrazide (AHY) (2), and DL-threo-β-hydroxyaspartate (βHA) (3) were selected.

25

Growth inhibition of <u>Escherichia coli</u> by these analog compounds is shown in Figs. 1-3. Further, growth recovery of <u>Escherichia coli</u>, in the case of addition of the aforementioned inhibition recovering substances alone or as a mixture of 2 species or 3 species, is shown in Figs. 4-6. In addition, as a control, growth in the case of addition of the inhibition recovering substance in the absence of the inhibitory substance is shown in Fig. 7. Incidentally, in Figs. 4-7, additives 1, 2 and 3 indicate nucleic acids, glutamic acid or amino acids of the aspartic acid family, respectively.

Further, inhibition of activity by the analog compound on phosphoenolpyruvate carboxylase was investigated. Crude enzyme was prepared from an <u>Escherichia coli</u> HB101 strain in accordance with a method described in <u>The Journal of Biochemistry</u>. Vol. 67, No. 4 (1970), and enzyme activity was measured in accordance with a method described in Eur. J. <u>Biochem.</u>, 202, 797-803 (1991).

Escherichia coli HB101 cultivated in an LB medium was disrupted, and a suspension was centrifuged to obtain a supernatant which was used as a crude enzyme solution. Measurement of enzyme activity was performed by measuring decrease in absorbance at 340 nm while allowing acetyl-coenzyme A known to affect the activity to exist at a concentration of 0.1 mM in a measurement system containing 2 mM potassium phosphoenolpyruvate, 0.1 mM NADH, 0.1 M Tris-acetate (pH 8.5), 1.5 U malate dehydrogenase and crude enzyme. Results are shown in Fig. 8.

According to the results as above, it is apparent that the aforementioned three compounds inhibit growth of Escherichia coli, this inhibition cannot be recovered by nucleic acids alone, but the inhibition can be recovered by addition of glutamic acid or amino acids of the aspartic acid family. Therefore, these analog compounds were postulated to be selective inhibitors of phosphoenolpyruvate carboxylase. As shown in Examples described below, by using these compounds, the present invention has succeeded in selection of an Escherichia coli which produces the mutant phosphoenolpyruvate carboxylase.

When a transformant having an aimed mutant enzyme gene is screened by using the aforementioned compounds, and a recombinant DNA is recovered, then the mutant enzyme gene is obtained. Alternatively, in the case of a mutation treatment of an microorganism itself, when a mutant strain having an aimed mutant enzyme gene is screened by using the aforementioned compounds, a DNA fragment containing the aimed mutant enzyme gene is isolated from the strain, and it is ligated with a suitable vector, then the mutant enzyme gene is obtained.

On the other hand, as a result of diligent investigation by the present inventors taking notice of importance of an arginine residue in an aspartate binding protein of <u>Escherichia coli</u> (Krikos, A., Mouth, N., Boyd, A. and Simon, M. I. <u>Cell</u>, 33, 615-622 (1983), Mowbray, S. L and Koshland, D. E. <u>J. Biol. Chem.</u>, 264, 15638-15643 (1990), Milburn, M. V., Prive, G. G., Milligan, D. L., Scott, W. G., Yeh, J., Jancarik, J., Koshland, D. E. and Kim, S. H., <u>Science</u>, 254, 1342-1347 (1991)), it has been found that inhibition by aspartic acid is substantially desensitized by converting 438th arginine of phosphoenolpyruvate carboxylase into cysteine. In order to convert 438th arginine into cysteine, a codon of 438th

arginine of a gene coding for phosphoenolpyruvate carboxylase may be converted into a codon of cysteine. For example, in SEQ ID NO:1, CGT of nucleotide numbers of 1548-1550 may be converted into TGT or TGC.

Further, the present inventors performed chemical modification of lysine residues of phosphoenolopyruvate carboxylase by using 2,4,6-trinitrobenzenesulfonic acid (TNBS) which is a compound to chemically modify lysine residues of a protein. During modification reaction, malic acid capable of serving as an inhibitor of phosphoenolopyruvate carboxylase was allowed to exist together. Namely, it was assumed that a lysine residue in the vicinity of a binding position of phosphoenolopyruvate carboxylase would be protected by bound malic acid and not be subjected to chemical modification. As a result, it was suggested that a 620th lysine residue was important for malic acid to bind phosphoenolopyruvate carboxylase, and it was found that the feedback inhibition by aspartic acid was desensitized while maintaining the enzyme activity of phosphoenolopyruvate carboxylase by converting the 620th lysine residue into a serine residue. In order to convert the 620th lysine residue into the serine residue, a codon of 620th lysine of the gene coding for phosphoenolopyruvate carboxylase may be converted into a codon of serine. For example, in SEQ ID NO:1, AAA having nucleotide numbers of 2094-2096 may be replaced with TCT, TCC, TCA, TCG, AGT or AGC.

In accordance with methods such as the Overlapping Extension method (Ho, S. N., Hunt, H. D., Horton, R. M., Pullen, J. K. and Pease, L. R., Gene, 77, 51-59 (1989)), the site specific mutation method (Kramer, W. and Frits, H. J., Meth. in Enzymol., 154, 350 (1987); Kunkel, T. A. et al., Meth. in Enzymol., 154, 367 (1987)) and the like, conversion of the codon can be also achieved by introducing mutation such as amino acid replacement, insertion, deletion and the like into a phosphoenolpyruvate carboxylase gene as a wild type enzyme gene or having another mutation. These methods are based on a principle that a non-mutated gene DNA is used as a template, and a synthetic DNA containing a mismatch at a mutation point is used as one of primers so as to synthesize complemental strands of the aforementioned gene DNA, thereby mutation is introduced. By using these methods, it is possible to cause intended mutation at an aimed site.

Alternatively, a sequence, which has restriction enzyme cleavage ends at both termini and contains both sides of a mutation point, is synthesized, and exchanged for a corresponding portion of a non-mutated gene, thereby mutation can be introduced (cassette mutation method).

The DNA fragment coding for the phosphoenolpyruvate carboxylase with mutation introduced as described above is expressed by using a suitable host-vector system, thereby it is possible to produce a mutant enzyme. Alternatively, even by performing transformation by integrating the DNA fragment of the present invention into a host chromosomal DNA, an aimed mutant enzyme can be produced.

As the host, there may be exemplified microorganisms belonging to the genus <u>Escherichia</u>, for example, <u>Escherichia coli</u>, coryneform bacteria and the like. The coryneform bacteria include bacteria belonging to the genus <u>Corynebacterium</u>, bacteria belonging to the genus <u>Brevibacterium</u> having been hitherto classified into the genus <u>Brevibacterium</u> but being united as bacteria belonging to the genus <u>Corynebacterium</u> at present, and bacteria belonging to the genus <u>Brevibacterium</u> closely related to bacteria belonging to the genus <u>Corynebacterium</u>. Incidentally, hosts which are preferable for amino acid production will be described below.

On the other hand, as the vector DNA, a plasmid vector is preferable, and those capable of self-replication in a host cell are preferable. When the host is <u>Escherichia coli</u>, for example, pUC19, pUC18, pBR322, pHSG299, pHSG399, RSF1010 and the like are exemplified. Alternatively, a vector of phage DNA can be also utilized.

Further, when the host is the coryneform bacteria, vectors which can be used and hosts which harbor them are exemplified below. Incidentally, deposition numbers of international depositories are shown in parentheses.

pAJ655 Escherichia coli AJ11882 (FERM BP-136)

Corynebacterium glutamicum SR8201 (ATCC 39135)

pAJ1844 <u>Escherichia coli</u> AJ11883 (FERM BP-137)

Corynebacterium glutamicum SR8202 (ATCC 39136)

pAJ611 Escherichia coli AJ11884 (FERM BP-138)

pAJ3148 Corynebacterium glutamicum SR8203 (ATCC 39137)

pAJ440 Bacillus subtilis AJ11901 (FERM BP-140)

These vectors may be obtained from the deposited microorganisms as follows. Cells collected at the logarithmic growth phase are subjected to bacteriolysis by using lysozyme and SDS, and centrifuged at $30000 \times g$ to obtain a supernatant solution from a lysate, to which polyethylene glycol is added to perform separation and purification of the vectors by means of cesium chloride-ethidium bromide equilibrium density gradient centrifugation.

In order to transform <u>Escherichia coli</u> with a recombinant vector obtained by inserting the DNA sequence of the present invention into the aforementioned vector, it is possible to use a method usually used for transformation of <u>Escherichia coli</u>, such as a method in which cells are treated with calcium chloride to enhance permeability of DNA (Mandel, M. and Higa, A., <u>J. Mol. Biol.</u>, 53, 159 (1977)) and the like.

Further, as a method for transforming the coryneform bacteria, there is the aforementioned method in which cells are treated with calcium chloride, or a method in which incorporation is performed at a specified growth period in which

cells can incorporate DNA (report in relation to <u>Bacillus subtilis</u> by Duncan, C. H. at al.). Further, incorporation into bacterial cells can be achieved by forming protoplasts or spheroplasts of DNA recipients which easily incorporate plasmid DNA. These are known for <u>Bacillus subtilis</u>, <u>Actinomyces</u> and yeast (Chang, S. et al., <u>Molec. Gen. Genet.</u>, 168, 111 (1979), Bibb et al., <u>Nature</u>, 274, 398 (1978), Hinnen, A. et al., <u>Proc. Natl. Acad. Sci. USA</u>, 75 1929 (1978)). Additionally, a method for transforming coryneform bacteria is disclosed in Japanese Patent Laid-open No. 2-207791.

In order to express the DNA sequence of the present invention in the aforementioned hosts, a promoter such as lac, trp, PL and the like which efficiently works in microorganisms may be used, or when the DNA sequence of the present invention contains a promoter of the phosphoenolopyruvate carboxylase gene, it may be used as it is. Alternatively, when the coryneform bacterium is used as the host, it is also possible to use a known trp promoter originating from a bacterium belonging to the genus <u>Brevibacterium</u> (Japanese Patent Laid-open No. 62-244382) and the like.

Further, as described above, it is acceptable that the DNA sequence of the present invention is inserted into the vector DNA capable of self-replication and introduced into the host to allow the host to harbor it as a plasmid, and it is also acceptable that the DNA sequence of the present invention is integrated into a chromosome of an microorganism by means of a method using transposon (Berg, D. E. and Berg, C. M., <u>Bio/Technol.</u>, 1, 417 (1983)), Mu phage (Japanese Patent Laid-open No. 2-109985) or homologous recombination (<u>Experiments in Molecular Genetics</u>, Cold Spring Harbor Lab. (1972)). In addition, in order to integrate the DNA of the present invention into the coryneform bacteria, it is possible to utilize a temperature-sensitive plasmid disclosed in Japanese Patent Laid-open No. 5-7491.

When the microorganism transformed with the DNA sequence of the present invention as described above is cultivated, and this DNA sequence is expressed, then a mutant enzyme is obtained. It becomes apparent, by measuring the activity by adding aspartic acid to an enzyme reaction system, whether or not the mutant enzyme thus obtained has desensitized feedback inhibition by aspartic acid. It is possible for the measurement of the enzyme activity to use a spectrometric method (Yoshinage, T., Izui, K. and Katsuki, H., J. Biochem., 68, 747-750 (1970)) and the like.

Further, the DNA sequence of the present invention codes for the mutant enzyme in which feedback inhibition by aspartic acid is desensitized, so that the microorganism harboring this DNA sequence can be utilized for efficient fermentative production of amino acids of the aspartic acid family and the glutamic acid family as described below.

Escherichia coli AJ12907, AJ12908, AJ12909 and AJ12910 harboring the mutant enzyme genes obtained in Examples described below are deposited in National Institute of Bioscience and Human Technology of Agency of Industrial Science and Technology (1-3, Higashi 1-chome, Tsukuba-shi, Ibaraki-ken, Japan; zip code 305) on August 3, 1993 under the deposition numbers of FERM P-13774, FERM P-13775, FERM P-13776 and FERM P-13777, transferred from the original deposition to international deposition based on Budapest Treaty on July 11, 1994 and has been deposited as deposition numbers of FERM BP-4734, FERM BP-4735, FERM BP-4736, FERM BP-4737, respectively in this order.

(3) Production method of amino acids

35

45

Amino acids can be produced by cultivating the microorganism harboring the DNA sequence of the present invention in a preferable medium, and separating generated amino acids. As such amino acids, there may be exemplified L-lysine, L-threonine, L-methionine, L-isoleucine, L-glutamic acid, L-arginine and L-proline.

Preferable hosts into which the DNA sequence of the present invention is introduced to be used for production of each of the amino acids, and a cultivation method will be exemplified below.

- (1) Hosts preferable for the amino acid production method of the present invention
- (i) Hosts preferable for L-lysine production

As the host to be used for L-lysine production according to the present invention, there may be exemplified bacteria belonging to the genus <u>Escherichia</u>, preferably L-lysine-producing <u>Escherichia</u> coli. Concretely, a mutant strain having resistance to a lysine analog can be exemplified. Such a lysine analog is those which inhibit growth of microorganisms belonging to the genus <u>Escherichia</u>, however, the suppression is totally or partially desensitized provided that L-lysine co-exits in the medium. For example, there are oxalysine, lysine hydroxamate, S-(2-aminoethyl)-cysteine (hereinafter abbreviated as "AEC"), γ-methyllysine, α-chlorocaprolactam and the like. Mutant strains having resistance to these lysine analogs can be obtained by applying an ordinary artificial mutation treatment to microorganisms belonging to the genus <u>Escherichia</u>. Concretely, as a bacterial strain to be used for L-lysine production, there may be exemplified <u>Escherichia coli</u> AJ11442 (deposited as FERM P-5084, see lower-left column on page 471 in Japanese Patent Laidopen No. 56-18596).

On the other hand, various artificial mutant strains of coryneform bacteria which have been used as L-lysine-producing bacteria can be used for the present invention. Such artificial mutant strains are as follows: AEC resistant mutant strain; mutant strain which requires amino acid such as L-homoserine for its growth (Japanese Patent Publication Nos. 48-28078 and 56-6499); mutant strain which exhibits resistance to AEC and requires amino acid such as L-leucine, L-

homoserine, L-proline, L-serine, L-arginine, L-alanine, L-valine and the like (United States Patent Nos. 3708395 and 3825472); L-lysine-producing mutant strain which exhibits resistance to DL-α-amino-ε-caprolactam, α-amino-lauryl-lactam, quinoid and N-lauroylleucine; L-lysine-producing mutant strain which exhibits resistance to an inhibitor of oxaloacetate decarboxylase or respiratory system enzyme (Japanese Patent Laid-open Nos. 50-53588, 50-31093, 52-102498, 53-86089, 55-9783, 55-9789, 56-32995 and 56-39778, and Japanese Patent Publication Nos. 53-43591 and 53-1833); L-lysine-producing mutant strain which requires inositol or acetic acid (Japanese Patent Laid-open Nos. 55-9784 and 56-8692); L-lysine-producing mutant strain which exhibits sensitivity to fluoropyruvate or temperature not less than 34 °C (Japanese Patent Laid-open Nos. 55-9783 and 53-86090); and mutant strain of Brevibacterium or Coryne-bacterium which exhibits resistance to ethylene glycol and produces L-lysine (see United States Patent Application Serial No. 333455).

Followings are exemplified as concrete coryneform bacteria to be used for lysine production:

(2) Cultivation method

15

20

25

30

35

40

45

50

The method for cultivating the aforementioned hosts is not especially different from a cultivation method for amino acid-producing microorganisms in the prior art. Namely, an ordinary medium is used containing a carbon source, a nitrogen source and inorganic ions, and optionally organic trace nutrients such as amino acids, vitamins and the like.

As the carbon source, glucose, sucrose, lactose and the like, as well as starch hydrolysate, whey, molasses and the like containing them may be used. As the nitrogen source, ammonia gas, aqueous ammonium, ammonium salt and the like can be used. Incidentally, when a nutrient requiring mutant strain for amino acids or the like is used as the host, it is necessary to suitably add the nutrient such as amino acid or the like required by the strain to the medium. An example of the medium for lysine production is shown in Table 1 below as a medium to be used for amino acid production. Incidentally, calcium carbonate is added to other components after being separately sterilized.

Table 1

Medium component	Blending amount
glucose	5 g/dl
(NH ₄) ₂ SO ₄	2.5 g/dl
KH ₂ PO ₄	0.2 g/dl
MgSO ₄ • 7H ₂ O	0.1 g/dl
yeast extract	0.05 g/dl
thiamine hydrochloride	1 μg/l
biotin	300 μg/l
FeSO ₄ • 7H ₂ O	1 mg/dl
MnSO ₄ • 4H ₂ O	1 mg/dl
calcium carbonate	2.5 g/dl
(pH 7.0)	

The cultivation is performed until generation and accumulation of amino acids substantially stop while suitably controlling pH and temperature of the medium under an aerobic condition. In order to collect amino acids thus accumulated in the cultivated medium, an ordinary method can be applied.

BRIEF DESCRIPTION OF THE DRAWINGS

 - Fig. 10 shows inhibition of phosphoenolpyruvate carboxylase of the present invention by aspartic acid.
 - Fig. 11 shows a method for introducing mutation into a phosphoenolpyruvate carboxylase gene.
- Fig. 12 shows influences exerted by aspartic acid on acitivities of wild type and mutant phosphoenolpyruvate carboxylase in which 438th arginine was substituted with cysteine counted from the N-terminus.
- Fig. 13 shows influences exerted by aspartic acid on activities of wild type and mutant phosphoenolpyruvate carboxylase in which 620th lysine was substituted with serine counted from the N-terminus.

BEST MODE FOR CARRYING OUT THE INVENTION

The present invention will be explained more concretely below with reference to Examples.

Example 1: acquisition of mutant phosphoenolpyruvate carboxylase gene

A mutant gene was prepared by using a plasmid pS2 obtained by inserting a phosphoenolpyruvat carboxylase gene having been cloned and determined for its base sequence into a <u>Sal</u>l site of a vector plasmid pBR322. pS2 has an ampicillin resistance gene as a drug resistance marker gene (Sabe, H. et al., <u>Gene</u>, 31, 279-283 (1984)). The nucleotide sequence of the phosphoenolpyruvate carboxylase gene contained in pS2 is the same as that contained in the aforementioned plasmid pT2.

pS2 DNA was treated at 75 °C for 2 hours with a hydroxylamine treating solution (20 μg/ml pS2 DNA, 0.05 M sodium phosphate (pH 6.0), 1 mM EDTA, 0.4 M hydroxylamine). Because of influence by pH on the hydroxylamine treatment, 80 μl of 1 M hydroxylamine • HCl and 1 mM EDTA solution having a pH adjusted to 6.0 with sodium hydroxide, 100 μl of 0.1 M sodium phosphate (pH 6.0) and 1 mM EDTA solution, and TE (10 mM Tris-HCl, 1 mM EDTA) buffer containing 2 μg of pS2 DNA were mixed, to finally provide 200 μl with water.

The aforementioned condition is a condition in which transformants has a survival ratio of 0.2 % based on a state before the treatment in an ampicillin-containing medium when <u>Escherichia coli</u> HB101 is transformed with pS2 after the treatment

Escherichia coli HB101 was transformed with pS2 treated with hydroxylamine, which was spread on a solid plate medium containing ampicillin to obtain about 10000 colonies of transformants. They were suspended in a liquid medium, and spread on a solid plate medium containing any one of 3-bromopyruvate (3BP), aspartate-β-hydroxamate (AHX), aspartate-β-hydrazide (AHY) and DL-threo-β-hydroxyaspartate (βHA) as the analog compounds of aspartic acid at a concentration near a minimal inhibitory concentration to give 10³ to 10⁵ cells per one medium plate, and growing colonies were selected.

From 100 strains of analog compound resistant strains thus obtained, phosphoenolpyruvate carboxylase produced by each of them was partially purified in accordance with a method described in <u>The Journal of Biochemistry</u>, Vol. 67, No. 4 (1970), and inhibition of enzyme activity by the analog compounds was investigated. Measurement of the enzyme activity was performed in the same manner as described above.

Further, plasmids were isolated from bacterial strains producing mutant enzymes with activities not inhibited by the analog compounds, and were introduced into <u>Escherichia coli</u> PCR1 as a phosphoenolpyruvate carboxylase deficient strain (Sabe, H. et al., <u>Gene</u>, 31, 279-283 (1984)), to confirm production of the mutant enzymes.

Five transformants harboring mutant enzyme genes were thus obtained. As a result of determination of base sequences of these genes, 2 strains had the same mutation, and 4 kinds of mutant genes were obtained. The transformants harboring them were designated as AJ12907, AJ12908, AJ12909 and AJ12910, and were deposited in National Institute of Bioscience and Human Technology of Agency of Industrial Science and Technology1-3, Higashi 1-chome, Tsukuba-shi, Ibaraki-ken, Japan; zip code 305) on August 3, 1993 under the deposition numbers of FERM P-13774, FERM P-13775, FERM P-13776 and FERM P-13777, transferred from the original deposition to international deposition based on Budapest Treaty on July 11, 1994 and has been deposited as deposition numbers of FERM BP-4734, FERM BP-4735, FERM BP-4736, FERM BP-4737, respectively in this order. Further, the plasmids possessed by them were designated as pBP5, pHA19, pBP122 and pR6 respectively in this order. Mutations possessed by the phosphoenolpyruvate carboxylase genes contained in each of the plasmids are shown in Table 2. Numerical values in the table indicate nucleotide numbers or amino acid numbers in SEQ ID NO:1.

40

Table 2

45

50

Transformant	Plasmid	Mutation	Amino acid replacement associated with mutation
AJ12907	pBP5	²¹⁰⁹ G→A	⁶²⁵ Glu→Lys
AJ12908	pHA19	⁹⁰¹ G→A	²²² Arg→His
		⁹⁰³ G→A	²²³ Glu→Lys
AJ12909	pBP122	¹⁰⁹⁹ C→T	²⁸⁸ Ser→Phe
ļ		¹¹⁰¹ G→A	²⁸⁹ Glu→Lys
		¹⁸⁸⁹ G→A	⁵⁵¹ Met→lle
	 	²⁶⁴⁶ G→A	⁸⁰⁴ Glu→Lys
AJ12910	pR6	²⁸³⁵ G→A	⁸⁶⁷ Ala→Thr

Incidentally, selection was performed for AJ12907 and AJ12909 in a medium containing 500 μ g/ml of 3BP, for AJ12908 in a medium containing 1000 μ g/ml of β HA, and for AJ12910 in a medium containing 500 μ g/ml of AHY.

Example 2: mutant phosphoenolpyruvate carboxylase

Sensitivity to aspartic acid was investigated for phosphoenolpyruvate carboxylases produced by the aforementioned 4 transformants. These bacterial strains are deficient in the phosphoenolpyruvate carboxylase gene originating from the host, so that produced phosphoenolpyruvate carboxylase originates from the plasmid.

Sensitivity to aspartic acid was investigated in accordance with a known method (Yoshinaga, T., Izui, K. and Katsuki, H., J. Biochem., 68, 747-750 (1970)). Namely, as a result of measurement of the enzyme activity produced by each of the transformants or <u>Escherichia coli</u> harboring pS2 in the presence of acetyl-coenzyme A known to affect the activity in an activity measurement system at a concentration of 0.1 mM or 1 mM, sensitivity to aspartic acid was measured as shown in Figs. 9 and 10.

According to the result, it is apparent that the wild type enzyme loses its activity when aspartic acid is at a high concentration, while the mutant phosphoenolpyruvate carboxylase of the present invention substantially continues to maintain its activity.

Example 3: fermentative production of L-threonine by Escherichia coli with introduced mutant phosphoenolpyruvate carboxylase

As threonine-producing bacteria of <u>Escherichia coli</u>, B-3996 strain (Japanese Patent Laid-open No. 3-501682 (PCT)) has the highest production ability among those known at present. Thus upon evaluation of the mutant phosphoenolpyruvate carboxylase, B-3996 was used as the host. This B-3996 strain has been deposited in Research Institute for Genetics and Industrial Microorganism Breeding under a registration number of RIA 1867. Further, pBP5 was selected as the mutant phosphoenolpyruvate carboxylase to be evaluated, which was subjected to an experiment.

The plasmid pBP5 having the mutant phosphoenolpyruvate carboxylase was introduced into <u>Escherichia coli</u> B-3996 in accordance with a method of Hanahan (<u>J. Mol. Biol.</u>, Vol. 106, p577 (1983)), and a transformant was isolated. As a control, <u>Escherichia coli</u> B-3996 was transformed in the same manner with pS2 as the plasmid to express the wild type phosphoenolpyruvate carboxylase gene.

When Escherichia coli B-3996 and the transformants therefrom were respectively inoculated in a 500 ml of Sakaguchi flask poured with 20 ml of a medium having a composition in Table 3, and cultivated at 37 °C for 40 hours to investigate a production amount of L-threonine, then results shown in Table 4 were obtained. Incidentally, the aforementioned medium was separated into two: glucose and MgSO₄ • 7H₂O, and the other components, and adjusted to have a pH of 7.0 with KOH followed by autoclaving at 115 °C for 10 minutes, and then, after mixing them, separately sterilized CaCO₃ was added by 30 g/l.

Table 3

lable 3									
Component	Blending amount (g/l)								
glucose	40								
(NH ₄) ₂ SO ₄	16								
KH ₂ PO ₄	1

Escherichia coli B-3996/pS2	15.8
Escherichia coli B-3996/pBP5	16.8

10

5

As clarified from the result, Escherichia coli B-3996/pBP5 harboring the mutant enzyme expression plasmid having the DNA sequence of the present invention had an improved threonine-producing ability as compared with Escherichia coli B-3996/pS2 harboring the plasmid to express the wild type enzyme.

15

Example4: fermentative production of L-alutamic acid by Escherichia coli with introduced mutant phosphoenolpyruvate carboxylase

As glutamic acid-producing bacteria of Escherichia coli, Escherichia coli AJ-12628 described in Japanese Patent Laid-open No. 4-11461 has the highest production ability among those known at present. Thus upon evaluation of the mutant phosphoenolpyruvate carboxylase, AJ-12628 was used as the host.

The AJ-12628 strain has been deposited in National Institute of Bioscience and Human Technology of Agency of Industrial Science and Technology under a registration number of FERM BP-385 Further, pBP5 was selected as the mutant phosphoenolpyruvate carboxylase to be evaluated, which was subjected to an experiment.

The plasmid pBP5 having the mutant phosphoenolpyruvate carboxylase was introduced into Escherichia coli AJ-12628 in accordance with a method of Hanahan (J. Mol. Biol., Vol. 106, p577 (1983)), and a transformant was isolated. In the same manner, a transformant of Escherichia coli AJ-12628 with pS2 was isolated.

When Escherichia coli AJ-12628 and the transformants therefrom were respectively inoculated in a 500 ml of Sakaguchi flask poured with 20 ml of a medium having a composition in Table 5, and cultivated at 37 °C for 36 hours to investigate a production amount of L-glutamic acid, then results shown in Table 6 were obtained. Incidentally, the aforementioned medium was separated into two: glucose and MgSO₄ • 7H₂O, and the other components, and adjusted to have a pH of 7.0 with KOH followed by autoclaving at 115 °C for 10 minutes, and then, after mixing them, separately sterilized CaCO3 was added by 30 g/l.

Escherichia coli AJ-12628/pBP5	19.6

10

As clarified from the result, <u>Escherichia coli</u> AJ-12628/pBP5 harboring the mutant enzyme expression plasmid having the DNA sequence of the present invention had an improved glutamate-producing ability as compared with <u>Escherichia coli</u> AJ-12628/pS2 harboring the plasmid to express the wild type enzyme.

15

Example 5: production of L-lysine by coryneform bacterium with introduced mutant phosphoenolpyruvate carboxylase

In order to introduce and express the mutant gene in a coryneform bacterium, a promoter originating from a bacterium belonging to the genus <u>Brevibacterium</u> was obtained, and was ligated with the mutant gene to prepare an expression type plasmid. Further, it was introduced into a bacterium belonging to the genus <u>Brevibacterium</u> to perform production of L-lysine.

(1) Acquisition of aspartokinase (AK) gene originating from bacterium belonging to the genus Brevibacterium

Chromosomal DNA was prepared according to an ordinary method from a <u>Brevibacterium lactofermentum</u> (<u>Corynebacterium glutamicum</u>) wild strain (ATCC 13869). An AK gene was amplified from the chromosomal DNA by PCR (polymerase chain reaction; see White, T. J. et al., <u>Trends Genet.</u>, 5, 185 (1989)). For DNA primers used in the amplification, an oligonucleotide of 23 mer (SEQ ID NO:3) and an oligonucleotide of 21 mer (SEQ ID NO:4) were synthesized to amplify a region of about 1643 bp coding for the AK gene based on a sequence known in <u>Corynebacterium glutamicum</u> (see <u>Molecular Microbiology</u> (1991) 5 (5), 1197-1204, <u>Mol. Gen. Genet.</u> (1990) 224, 317-324).

The synthesis of DNA was performed in accordance with an ordinary phosphoamidite method (see <u>Tetrahedron Letters</u> (1981), 22, 1859) using a DNA synthesizer model 380B produced by Applied Biosystems Co. In the PCR reaction, DNA Thermal Cycler PJ2000 type produced by Takara Shuzo Co., Ltd. was used, and gene amplification was performed by using <u>Taq</u> DNA polymerase in accordance with a method designated by the manufacturer.

An amplified gene fragment of 1643 kb was confirmed by agarose gel electrophoresis, and then the fragment cut out from the gel was purified by an ordinary method, and was cleaved with restriction enzymes Nrul (produced by Takara Shuzo Co., Ltd.) and EcoRI (produced by Takara Shuzo Co., Ltd.). pHSG399 (see Takeshita, S. et al.; Gene (1987), 61, 63-74) was used for a cloning vector for the gene fragment. pHSG399 was cleaved with a restriction enzyme Smal (produced by Takara Shuzo Co., Ltd.) and a restriction enzyme EcoRI, and ligated with the amplified AK gene fragment.

Ligation of DNA was performed by a designated method by using a DNA ligation kit (produced by Takara Shuzo Co., Ltd.). In such a manner, a plasmid was manufactured in which pHSG399 was ligated with the AK gene fragment amplified from Brevibacterium chromosome. The plasmid having the AK gene originating from ATCC 13869 as the wild strain was designated as p399AKY.

45

(2) Determination of base sequence of AK gene of Brevibacterium lactofermentum

The AK plasmid, p399AKY was prepared, and the base sequence of the AK gene was determined. Determination of the base sequence was performed in accordance with the method of Sanger et al.: (F. Sanger et al.: Proc. Natl. Acad. Sci. USA, 74, 5463 (1977) and so forth). Results are shown in SEQ ID NO:5 and SEQ ID NO:7. The DNA fragments have two open reading frames which correspond to α -subunit and β -subunit of AK, respectively. In SEQ ID NO:5 and SEQ ID NO:7, amino acid sequences corresponding to each of the open reading frames are shown together with nucleotide sequences. Further, only the amino acid sequences corresponding to each of the open reading frames are shown in SEQ ID NO:6 and SEQ ID NO:8.

5

(3) Preparation of phosphoenolpyruvate carboxylase expression plasmid

<u>Sall</u> fragments of about 4.4 kb containing phosphoenolpyruvate carboxylase genes were extracted from pS2 as the plasmid having the wild type phosphoenolpyruvate carboxylase gene and pBP5 as the plasmid having the obtained

mutant phosphoenolpyruvate carboxylase gene, and inserted into a <u>Sal</u>l site of a plasmid vector pHSG399 universally used for <u>Escherichia coli</u>. Manufactured plasmids were designated as pHS2 for the wild type and as pHBP5 for the mutant.

In order to convert pHS2 and pHPB5 into plasmids to express in <u>Brevibacterium</u>, a promoter and a replication origin of a plasmid for functioning in <u>Brevibacterium</u> were introduced. As the promoter, a gene fragment containing one from 1st <u>Nru</u>l site to 207th <u>Apa</u>Ll site of the base sequence, which was postulated to be a promoter region of the cloned AK gene, was extracted from p399AKY, and inserted into an <u>Ava</u>l site located about 60 bp before the structural genes of pHS2 and pHBP5 to allow the transcription direction to be in a regular direction.

Further, a gene fragment to enable autonomously replication of the plasmid in <u>Brevibacterium</u>, namely the replication origin of the plasmid was introduced into a site located on the vector. A gene fragment containing the replication origin of the plasmid was extracted from a vector pHC4 for <u>Brevibacterium</u> (see paragraph No. 10 in Japanese Patent Laid-open No. 5-7491; <u>Escherichia coli</u> AJ12039 harboring the same plasmid is deposited in National Institute of Bioscience and Human Technology of Agency of Industrial Science and Technology, to which a deposition number of FERM P12215 is given), and restriction enzyme sites at both termini were modified into <u>Pst</u>I sites by introduction of linkers

This fragment was introduced into a <u>Pst</u>I site in a vector portion of the plasmid added with the promoter derived from <u>Brevibacterium</u>. Constructed phosphoenolpyruvate carboxylase-expressing plasmids were designated as pHS2B for a wild type phosphoenolpyruvate carboxylase plasmid originating from pS2 and as pHBP5B for a mutant phosphoenolpyruvate carboxylase plasmid originating from pBP5, respectively.

(4) Production of L-lysine by using phosphoenolpyruvate carboxylase expression type plasmid

Prepared pHS2B and pHBP5B were respectively introduced into AJ3463 as an L-lysine-producing bacterium of <u>Brevibacterium lactofermentum</u> (see Japanese Patent Publication No. 51-34477). For introduction of the gene, a transformation method employing electric pulse was used (see Japanese Patent Laid-open No. 2-207791). The host strain and transformants were cultivated with shaking for 72 hours at 31.5 °C in a lysine production medium having a composition in Table 7. The aforementioned medium was prepared such that those except for CaCO₃ among the components listed in the table were added to 1 I of water, and adjusted to have a pH of 8.0 with KOH followed by autoclaving at 115 °C for 15 minutes, and then CaCO₃ having been subjected to heat sterilization was further added. Accumulated amounts of L-lysine in the medium after cultivation are shown in Table 8.

Table 7

Component	Blending amount in 1 L
glucose	100 g
(NH ₄) ₂ SO ₄	55 g

Brevibac	terium lactofermentum AJ3463/pHBP5B	25.0

As shown in the result, <u>Brevibacterium lactofermentum</u> AJ3463/pHBP5B harboring the mutant enzyme expression plasmid having the DNA sequence of the present invention had an improved lysine-producing ability as compared with <u>Brevibacterium lactofermentum</u> AJ3463/pHS2B harboring the plasmid to express the wild type enzyme.

Example 6: another example of mutant phosphoenolpyruvate carboxylase of the present invention and its gene

(1) Preparation of mutant phosphoenolpyruvate carboxylase gene

5

10

20

Upon preparation of DNA coding for a mutant phosphoenolpyruvate carboxylase, a phosphoenolpyruvate carboxylase gene cloned in a plasmid pT2 was used as a material.

A host, which is allowed to harbor the plasmid pT2, is preferably deficient in phosphoenolpyruvate carboxylase gene in order to detect only the activity of phosphoenolpyruvate carboxylase originating from the plasmid. Escherichia coli F15 (Hfr, recA1, met, Δ(ppc-argECBH), Tn10) was used as such a deficient strain. Escherichia coli AJ-12873, which is allowed to harbor pT2 in F15 strain, is deposited as FERM P-13752 in National Institute of Bioscience and Human Technology of Agency of Industrial Science and Technology (1-3, Higashi 1-chome, Tsukuba-shi, Ibaraki-ken, Japan; zip code 305) on July 15, 1993, transferred from the original deposition to international deposition based on Budapest Treaty on

July 11, 1994 and has been deposited as deposition number of FERM BP-4732. In addition, an entire base sequence of pT2 is shown in SEQUENCE ID NO:1.

In order to replace a codon of 438th arginine of the phosphoenolpyruvate carboxylase into a codon of cysteine by using pT2, the Overlapping Extension method (Ho, S. N., Hunt, H. D., Horton, R. M., Pullen, J. K. and Pease, L. R., Gene, 77, 51-59 (1989)) utilizing the PCR (Polymerase Chain Reaction) method was used.

Incidentally, the PCR method is a method in which an amplification cycle comprising thermal denaturation of double strand DNA into single strand DNA, annealing of oligonucleotide primers corresponding to sequences at both ends of a site aimed to be amplified and the aforementioned thermally denatured DNA, and polymerase reaction using the aforementioned oligonucleotides as primers is repeated, thereby the aforementioned DNA sequence is amplified in a manner of an exponential function.

A region subjected to site specific mutation by the PCR method is shown in Fig. 11. The primers used in the present invention were 4 species of a primer c (SEQUENCE ID NO:11, corresponding to base Nos. 1535-1554 in SEQUENCE ID NO:1) having a sequence in the vicinity of the codon of 438th arginine, a primer b (SEQUENCE ID NO:10) having a sequence complement to the primer c, a primer a (SEQUENCE ID NO:9, corresponding to base Nos. 1185-1200 in SEQUENCE ID NO:1) having a sequence upstream therefrom, and a primer d (SEQUENCE ID NO:12, corresponding to base Nos. 2327-2342 in SEQUENCE ID NO:1) having a sequence complement to a downstream sequence.

In the primer b and the primer c, the codon (CGT) of 438th arginine was replaced with a codon (TGT) of cysteine. This replacement may use TGC which is another codon of cysteine. Further, C of the third letter of a codon (AAC) of 435th asparagine was replaced with T, and hence an <u>EcoRI</u> site was internally introduced with no replacement of amino acid, so that a mutant plasmid could be selected by using it as an index. However, this mutation is not essential to the present invention.

When the PCR reaction was performed by using pT2 DNA as a template and the primer a and the primer b as the primers, a fragment from the upstream of the mutation site to the mutation site (AB fragment in Fig. 11) was amplified. Further, when the PCR reaction was performed by using the primer c and the primer d, a fragment downstream from the mutation site (CD fragment in Fig. 11) was amplified. When each of the amplified products (AB, CD) was annealed again after thermal denaturation to perform a polymerase reaction, they were ligated to obtain a fragment (AD fragment in Fig. 11). Incidentally, the PCR reaction was performed by repeating 30 cycles of each comprising heating at 94 °C for 1 minute followed by denaturation (94 °C, 1.5 minutes), annealing (50 °C, 2 minutes), and elongation reaction by polymerase (72 °C, 3.5 minutes). In addition, reaction compositions are shown in Table 9.

Table 9

Composition ((): final conc.)	PC	CR fragme	ent
	AB	CD	AD
H ₂ O	53.5	53.5	53.5
10-fold reaction buffer	10	10	10
mixture of 1.25 mM dNTP	16	16	16
20 μM primer a (1 μM)	5	•	5
20 μM primer b (1 μM)	5	-	
20 μM primer c (1 μM)	-	5	•
20 μM primer d (1 μM)	-	5	5
10 μg/μl pT2 (0.1 μg)	10	10	-
PCR fragment AB*	-	-	5
PCR fragment CD*	-	-	5
2.5 U/μΙ <u>Taq</u> polymerase	0.5	0.5	0.5
total amount	100 μ	100 μl	100 µl

^{*:} PCR fragments AB and CD were prepared, after the PCR reaction, by recovering 10 μ l thereof from polyacrylamide gel, and dissolving it in 5 μ l of TE (10 mM Tris-HCl (pH 8.0), 1 mM EDTA (pH 8.0)).

In the AD fragment obtained as described above, a <u>Bss</u>HII site (1231-1236 in SEQ ID NO:1) at the upstream side and a <u>SpII</u> site (2249-2254 in SEQ ID NO:1) at the downstream side were present, so that complete digestion was performed with these enzymes to make replacement for a corresponding region of the plasmid pT2 (Fig. 11).

(2) Selection of inhibition-desensitized phosphoenolpyruvate carboxylase

5

10

15

20

25

30

50

Escherichia coli was transformed with a plasmid obtained as described above, and a transformed strain was cultivated to recover the plasmid to select one cleaved by <u>EcoRI</u>. With respect to selected DNA, a base sequence of the region amplified by the aforementioned PCR method was determined by the dideoxy method to confirm that base replacement as exactly aimed was introduced. This plasmid was designated as pT2R438C. A strain (AJ12874) obtained by introducing this plasmid into the aforementioned <u>Escherichia coli</u> F15 has been deposited as FERM P-13753 in National Institute of Bioscience and Human Technology of Agency of Industrial Science and Technology (1-3, Higashi 1-chome, Tsukuba-shi, Ibaraki-ken, Japan; zip code 305) on July 15, 1993, transferred from the original deposition to international deposition based on Budapest Treaty on July 11, 1994 and has been deposited as deposition number of FERM BP-4733.

The base sequence of pT2R438C is a sequence in which 1541th and 1550th nucleotides are replaced from C to T respectively in SEQ ID NO:1.

(3) Confirmation of desensitization of inhibition of mutant phosphoenolpyruvate carboxylase by aspartic acid

Sensitivity to aspartic acid was investigated for phosphoenolpyruvate carboxylase produced by the aforementioned <u>Escherichia coli</u> AJ12874 harboring pT2R438C. Incidentally, as described above, because the <u>Escherichia coli</u> F15 is deficient in phosphoenolpyruvate carboxylase, phosphoenolpyruvate carboxylase produced by AJ12874 originates from the plasmid.

Sensitivity to aspartic acid was investigated in accordance with a known method (Yoshinaga, T., Izui, K. and Katsuki, H., J. Biochem., 68, 747-750 (1970)). Namely, as a result of measurement of the enzyme activity in the presence of acetyl-coenzyme A known to affect the activity in an activity measurement system at a concentration of 1 mM or 2 mM, sensitivity to aspartic acid was measured as shown in Fig. 12.

It is apparent that the wild type enzyme substantially loses its activity when aspartic acid is at a high concentration, while the mutant phosphoenolpyruvate carboxylase of the present invention continues to maintain its activity.

(4) Preparation of mutant phosphoenolpyruvate carboxylase gene (II)

In order to replace a codon of 620th lysine with a codon of serine in the phosphoenolpyruvate carboxylase gene carried on the plasmid pT2, the Overlapping Extension method (Ho, S.N., Hunt, H.D., Horton, R.M., Pullen, J.K. and Pease, L.R., <u>Gene</u>, 77, 5I-59 (I989)) utilizing the PCR (Polymerase Chain Reaction) method was used. Concrete procedures were in accordance with the method described in (1). A plasmid carrying a mutant gene constructed with aimed replacement was designated as pT2K620S. Further, an obtained mutant enzyme was designated as K620S mutant enzyme.

(5) Confirmation of desensitization of inhibition by aspartic acid concerning mutant phosphoenolpyruvate carboxylase.

With respect to the phosphoenolpyruvic carboxylase produced by a transformant obtained by introducing the plasmid pT2K620S into the aforementioned <u>Escherichia coli</u> FI5, sensitivity to aspartic acid was investigated. Incidentally, as described above, since the <u>Escherichia coli</u> FI5 lacks phosphoenolpyruvate carboxylase, any phosphoenolpyruvate carboxylase produced by the transformant originates from the plasmid.

Sensitivity to aspartic acid was investigated in accordance with a known method (Yoshinaga, T., Izui, K. and Katsuki, H., <u>J. Biochem.</u>, 68, 747-750 (I970)). Namely, as a result of measurement of the enzyme activity in the presence of acetyl-coenzyme A known to affect the activity in an activity measurement system at a concentration of I mM or 2 mM, sensitivity to aspartic acid was measured as shown in Fig. 13.

It is apparent that the wild enzyme substantially loses its activity when aspartic acid is at a high concentration, while the type phosphoenolpyruvate carboxylase of the present invention continues to maintain its activity.

In Fig. I3, sensitivity to aspartic acid is also depicted for a mutant phosphoenolpyruvate carboxylase in which 650th lysine is replaced with serine (K650A mutant enzyme), and for a mutant phosphoenolpyruvate carboxylase in which 491th lysine is replaced with serine (K491A mutant enzyme). In the case of these mutant enzymes, inhibition by aspartic acid was not desensitized.

INDUSTRIAL APPLICABILITY

5

40

45

50

55

The DNA sequence of the present invention codes for the mutant phosphoenolpyruvate carboxylase, and the microorganism harboring this DNA sequence produces the aforementioned enzyme.

The mutant phosphoenolpyruvate carboxylase of the present invention does not substantially undergo activity inhibition by aspartic acid, so that it can be utilized for fermentative production of amino acids subjected to regulation of biosynthesis by aspartic acid and the like.

Claims

40

50

55

- A mutant phosphoenolpyruvate carboxylase originating from a microorganism belonging to the genus <u>Escherichia</u>,
   wherein said mutant phosphoenolpyruvate carboxylase has mutation to desensitize feedback inhibition of the phosphoenolpyruvate carboxylase by aspartic acid.
  - 2. A mutant phosphoenolpyruvate carboxylase according to claim 1, which, in the case of being allowed to exist in cells of a microorganism belonging to the genus <u>Escherichi</u>a, gives the cells resistance to a compound having the following properties:

it exhibits a growth inhibitory action against a microorganism belonging to the genus <u>Escherichia</u> which produces a wild type phosphoenolpyruvate carboxylase;

said growth inhibitory action is recovered by existence of L-glutamic acid or L-aspartic acid; and it inhibits wild type phosphoenolpyruvate carboxylase activity.

3. A mutant phosphoenolpyruvate carboxylase according to claim 2, wherein said compound is selected from 3-bromopyruvate, aspartic acid-β-hydrazide and DL-threo-β-hydroxyaspartic acid.

- 4. A mutant phosphoenolpyruvate carboxylase according to claim 1, wherein said mutation is mutation to replace 625th glutamic acid with lysine as counted from the N-terminus of the phosphoenolpyruvate carboxylase.
- 5. A mutant phosphoenolpyruvate carboxylase according to claim 1, wherein said mutation is mutation to replace 222th arginine with histidine and 223th glutamic acid with lysine respectively as counted from the N-terminus of the phosphoenolpyruvate carboxylase.
  - 6. A mutant phosphoenolpyruvate carboxylase according to claim 1, wherein said mutation is mutation to replace 288th serine with phenylalanine, 289th glutamic acid with lysine, 551th methionine with isoleucine and 804th glutamic acid with lysine respectively as counted from the N-terminus of the phosphoenolpyruvate carboxylase.
  - 7. A mutant phosphoenolpyruvate carboxylase according to claim 1, wherein said mutation is mutation to replace 867th alanine with threonine as counted from the N-terminus of the phosphoenolpyruvate carboxylase.
- 8. A mutant phosphoenolpyruvate carboxylase according to claim 1, wherein said mutation is mutation to replace 438th arginine with cysteine as counted from the N-terminus of the phosphoenolpyruvate carboxylase.
  - 9. A mutant phosphoenolpyruvate carboxylase according to claim 1, wherein said mutation is mutation to replace 620th lysine with serine as counted from the N-terminus of the phosphoenolpyruvate carboxylase.
  - A DNA fragment which codes for the mutant phosphoenolpyruvate carboxylase according to any one of claims 1 to
     9.
- 11. A microorganism belonging to the genus <u>Escherichia</u> or coryneform bacteria, transformed by allowing the DNA fragment according to claim 10 to be integrated in chromosomal DNA.
  - 12. A recombinant DNA formed by ligating the DNA fragment according to claim 10 with a vector DNA capable of autonomously replication in cells of bacteria belonging to the genus <u>Escherichia</u> or coryneform bacteria.
- 30 13. A microorganism belonging to the genus <u>Escherichia</u> or coryneform bacteria, transformed with the recombinant DNA according to claim 12.
  - 14. A method of producing amino acid, comprising:

10

20

35

40

45

50

55

cultivating the microorganism according to claim 11 or 13 in a suitable medium; and separating, from the medium, an amino acid selected from the group consisting of L-lysine, L-threonine, L-methionine, L-isoleucine, L-glutamic acid, L-arginine and L-proline.
